

Illustration and Writing Contest - Now and Future 2020 vs 2030

Scientists have high confidence that global temperatures will continue to rise for decades to come, largely due to greenhouse gases produced by human activities. I think global warming will become more and more serious in next few years. Maybe the loss of sea ice has accelerated sea level rise and has contributed to longer, more intense heatwaves. The current global warming has affected the ice on rivers and lakes which breaks up earlier, then the distribution of plants and animals has shifted and trees are flowering sooner. Because the Earth is getting hotter and hotter there is a shortage of water in many places. I think there may be drought everywhere in the future. So I draw this picture to warn others. I don't want the future to be like this. Hopefully everything will be better.
